

MARYLAND HEIGHTS FIRE PROTECTION DISTRICT

SMOKE DETECTORS FACTS AND FREQUENTLY ASKED QUESTIONS

How effective are smoke detectors?

Residential fire deaths have decreased steadily as the number of homes with smoke detectors has increased. Reports from the National Fire Protection Association on residential fire deaths show that you have a 40-50 percent better chance of surviving a fire if your home has the recommended number of smoke detectors.

Should I replace my smoke detector?

Smoke detectors that are ten years old are near the end of their service life and should be replaced. A smoke detector constantly monitors the air twenty-four hours a day. At the end of 10 years, it has gone through more than 3.5 million monitoring cycles. After this much use, components become less reliable. As the detector gets older, there is potential for failure and replacing them after 10 years reduces this possibility.

My detectors are wired into my electrical system. Do I need to replace them as often as battery-operated detectors?

Yes. Both types of detectors are equally affected by age.

How many detectors should I have?

The average sized home or apartment needs more than one smoke detector. The exact number depends on the number of levels in the home and the number of bedrooms. National fire safety standards recommend a minimum of one detector on each level of the home, one detector outside the bedroom area, and one in each bedroom. The detector that is placed outside of the bedroom area should be installed near enough to be heard at night through a closed bedroom door.

Are there different types of smoke detectors and what is the difference?

There are two types of smoke detectors for homes. One type is called an ionization detector because it monitors "ions," or electrically charged particles. Smoke particles entering the sensing chamber and change the electrical balance of the air. The detector's horn will sound when the change in electrical balance reaches a preset level. The other type of detector is called photoelectric because its sensing chamber uses a beam of light and a light sensor. Smoke particles entering the chamber change the amount of light that reaches the light sensor. The detector sounds when the smoke density reaches a preset level.

Is one type of detector better?

The ionization detector responds faster to small smoke particles, while the photoelectric responds faster to larger smoke particles. As a rule of thumb, fast-flaming fires produce more small smoke particles and smoldering fires produce larger particles. Thus, the response time of the two types of detectors vary, depending on the mix of small and large smoke particles in the fire. Independent laboratory test results show that the differences in response time are small enough that both types provide enough time to escape.

What is more important, the type of detector or the number of them?

The number of detectors is more important than the type. Installing several smoke detectors of each type will provide better coverage in the extreme cases of long-term smoldering or fast flaming fires. But since both types of detector will respond in time to escape, the most important thing is to install enough detectors in the proper locations.

Detectors are available with both types of sensors in the same unit, but they are more expensive than models with a single sensor. If the choice is between having only one of each type or having more of the same type, more detectors is the better choice.

My detector goes off when I cook. How can I stop this?

Smoke detectors are designed to be very sensitive so they will alert occupants to a fire in time for them to escape. If a detector regularly responds to smoke from cooking, there are several options for handling this problem. One way is to move the smoke detector farther away, giving the smoke a chance to dissipate. Moving a ceiling-mounted detector to a wall can also reduce nuisance alarms. However, this will also make it a little slower to respond to a real fire.

How can I test my detector?

Every smoke detector comes with a test button. We recommend that people test their detectors regularly, at least once a month.

Should I use real smoke to test my detectors?

This is not recommended, because the burning objects used to create the smoke might cause a fire. Some stores sell pressurized cans of simulated smoke for this purpose. Remember to always follow the directions printed on the label.

How important is it to clean my detectors?

Cleaning is easy. Just vacuum the detector once a month. This can be accomplished with a vacuum cleaner or by removing the cover and using a dusting brush. This will keep the sensing chamber free of dust, residue from cooking, and insects.

What about changing batteries?

Smoke detector batteries should last at least one year under normal conditions. The biggest reason that smoke detectors don't work is because people remove the batteries, e.g. to stop the low battery signal or a nuisance alarm, and then forget to replace them. When a battery reaches the end of its service life, the detector will give a short beep every minute or so. It is easy to remove the battery and then forget to replace it. The best way to prevent this is to replace batteries at the same time each year before the low battery signal begins. The Maryland Heights Fire Protection District suggests replacing smoke detector batteries when you change your clock in the fall.

For your convenience, the Maryland Heights Fire Protection District offers FREE smoke detectors and batteries to district residents who need them. For further information, contact the Administration Office at 298-4400, during normal business hours.
